

Proposal - Ecosystem responses to escalating drivers: linking species interactions and resilience

Fernando Cagua

The intensity of human generated drivers—climate change, land use, defaunation, nutrient enrichment, and biotic invasions—is increasing, and the trend is likely to continue¹. Those drivers are heavily modifying the functioning of many of the ecosystems we depend on². On the other hand, species in an ecological community form an network of interactions of tremendous importance for example, for the provision of ecosystem functioning, the provision of services, the maintenance of global biodiversity, and biogeochemical cycles³⁻⁶.

The overall objective of my proposed research is to improve our current understanding of the ecosystems response to multiple anthropogenic drivers and their cumulative impacts. In particular, I will focus on the role that networks of species interactions have in modulating the resilience of ecosystems—the amount of disturbance a system can withstand without entering a regime shift⁷.

Regime shifts are large, persistent changes in the function and structure of the ecosystem⁸—like the (often sudden) shift from a transparent to a turbid lake, from a woodland to a grassy landscape, from a self-sustaining fishery to a collapsed one, or from a coral dominated reef to one dominated by algae⁹. A necessary step to anticipate, prevent and reverse unwanted regime shifts caused by drivers of environmental change, is to understand the processes that support or undermine resilience and the role played by species interactions^{10,11}.

Despite the fact that the effect of those drivers permeates across entire communities, our understanding of their impacts is mostly based on studies of one or a few species. For my research I will use a complex network approach, which recognises that species live within a community, and that they interact between them. This approach—built upon tools from statistical physics and the social sciences—has been key in revealing structural patterns that transcend specific ecosystems¹²⁻¹⁴. Using a combination of complex system theory, population models, resilience theory and previously published empirical data I aim to untangle the mechanisms that link species interactions with the ecosystem’s resilience to environmental drivers of change.

As a model system, I will use mutualistic plant-pollinator networks, which are critical for global food production and biodiversity maintenance^{15,16}. Initially I will use biotic invasions as the environmental driver. Because of the paucity of empirical observations of network dynamics subject to invasions, I will simulate community-wide interspecies coexistence dynamics, and explicitly quantify the stability of the system from population fluctuations^{17,18}. This approach will enable me to predict how the structural and dynamic characteristics of the network determine the “invasibility” of an ecosystem, and when invasions are likely to lead to a regime shift^{19,20}.

Biotic invasions often act over ecosystems that are already degraded²¹. Using a similar methodology as for the species invasions, I will follow by studying how defaunation—from a functional perspective—affect the pre-invasion ecosystem resilience. Although some species (like beavers for example) are functionally unique in the ecosystem, some others are redundant in that they contribute in similar ways to an ecosystem function²². Despite theoretical and empirical evidence showing that the degree of functional redundancy has major effects on ecosystem stability and species coexistence²³⁻²⁸, we still don’t know how diversity within functional groups maps into different stability domains in the ecosystem²⁰.

The final objective of my proposed research is to translate the gained insight into useful lessons for ecosystem management. Recent work has highlighted that it is possible to control a complex network, by inducing perturbations that compensate previous disturbances²⁹. However this approach has never been used in ecology. I propose to expand this method to find the minimum number of species that have to be directly managed to move the ecosystem from one state to another, or to rescue one at the bring of failure. To do that I will use empirical and simulated networks from ecosystems that have undergone a regime shift to evaluate the feasibility of such and approach and it's management consequences.

Over the last years I have been focused on studying the ecology of tropical marine organisms. Through my previous research I have withnessed how entire ecosystems transform due to human pressures. Understanding what makes ecosystems vulnerable, and how to prevent and revert those undersirable transformations—not only on marine ecosystems—became my top scientific interest; I want to answer fundamental questions in ecology and ultimately improve the management of the ecosystems I love. I am aware long term goal that is likely to guide my scientific career for the next decade. My proposed PhD research, and the support from the NZIDRS, are going to be instrumental to reach those goals.
